# TWO UNIQUE PRIMITIVE PYTHAGOREAN TRIPLES FROM EVERY INTEGER 

Harry Z. Davis*

Keywords:
PythagoreanTriples.

## ABSTRACT

In this paper we show that for every integer, there are two unique primitive solutions to the classical Pythagorean equation. These solutions have two interesting points. The two unique primitive triples correspond to every integer, with no additional conditions. Two, for each of the solutions, $C$ - $B$ is the set of all odd integers squared.

## 1. PYTHAGOREAN TRIPLES

Consider the Pythagorean triple:

$$
\mathrm{A}^{2}+\mathrm{B}^{2}=\mathrm{C}^{2}
$$

where $\mathrm{A}, \mathrm{B}$, and C are all positive integers. The triple is a primitive triple if $\mathrm{A}, \mathrm{B}$ and C are relatively prime ${ }^{\text {a }}$.

[^0]The general Euclidean solution is, $A=M^{2}-N^{2}, B=2 M N, C=M^{2}+N^{2}$, where $M>N>$ 0 . To generate primitive triples, one must add two conditions, M and N must be relatively prime, and either M or N must be even ${ }^{\mathrm{b}}$.

In Appendix A we show that for every integer, I, there are two unique primitive solutions (each of which is just a special case of the general Euclidean solution ${ }^{c}$ ). There are three interesting points about these solutions. One, they generate two unique primitive triples for every integer, with no additional conditions. Two, for each of the solutions, C B is the set of all odd integers squared. Three, the solutions uses an analysis of $\mathrm{C}-\mathrm{A}$, rather than the factoring approach used in the standard Euclidean analysis.

One solution is: $A=4 I^{2}-1, B=4 I, C=4 I^{2}+1$. An interesting result, is that $C-B=(2 I$ $-1)^{2}$. In other words, for the set of solutions, $\mathrm{C}-\mathrm{B}$ is the set of all odd integers squared. Another interesting result, is that $\mathrm{C} / \mathrm{B}=\mathrm{I}+1 / 4 \mathrm{I}$, which approaches I as I gets larger.

A second solution, totally different than the first solution ${ }^{\text {d }}$, is: $\mathrm{A}=(2 \mathrm{I}+1)^{2}-4, \mathrm{~B}=4(2 \mathrm{I}$ $+1), \mathrm{C}=(2 \mathrm{I}+1)^{2}+4$. An interesting result, is that again $\mathrm{C}-\mathrm{B}=(2 \mathrm{I}-1)^{2}$, so that $\mathrm{C}-\mathrm{B}$ is the set of all odd integers squared. Another interesting result, is that $2(\mathrm{C} / \mathrm{B}-1)=\mathrm{I}+2 /(2 \mathrm{I}$ +1 ), which approaches I as I gets larger.

Table 1 presents a summary. Table 2 provides the mapping of the two solutions for every integer from 1 to 50 .

Table 1. Summary of Solutions

|  | Solution 1 | Solution 2 |
| :--- | :---: | :---: |
| A(I) | $\mathrm{A}=4 \mathrm{I}^{2}-1$ | $\mathrm{~A}=(2 \mathrm{I}+1)^{2}-4$ |
| $\mathrm{~B}(\mathrm{I})$ | $\mathrm{B}=4 \mathrm{I}$ | $\mathrm{B}=4(2 \mathrm{I}+1)$ |
| $\mathrm{C}(\mathrm{I})$ | $\mathrm{C}=4 \mathrm{I}^{2}+1$ | $\mathrm{C}=(2 \mathrm{I}+1)^{2}+4$ |
| Euclidean Solution | $\mathrm{N}=1$, <br> $\mathrm{M}=2 \mathrm{I}$ | $\mathrm{N}=2, \mathrm{M}=2 \mathrm{I}+1$ |
| C- A | 2 | 8 |
| (C-B) $)^{1 / 2}$ | $2 \mathrm{I}-1$ (the set of all odd positive |  |
| integers $)$ |  |  |

Table 2. Mapping of Two Solutions for Every Integer From 1 to 50

|  | Case 1 |  |  |  |  |  | Case 2 |  |  |  |  |  |

## Appendix:

## Lemma 1: For three integers $\mathbf{A}+\mathbf{B}=\mathbf{C}$, all three must be even, or two must be odd and one must be even.

It is impossible for all three to be odd, or for two to be even and one to be odd.
Proof: Assume all three are odd, $\mathrm{A}=2 \mathrm{~S}+1, \mathrm{~B}=2 \mathrm{~T}+1, \mathrm{C}=2 \mathrm{U}+1$. Then $\mathrm{A}=\mathrm{B}+\mathrm{C}$ becomes:

$$
2(\mathrm{~S}+\mathrm{T}+1-\mathrm{U})=1
$$

Since the left-hand side of the equation is even, the right side can't equal 1 , which is odd. So, all three terms can't be odd.

Assume two terms are even and one is odd, $\mathrm{A}=2 \mathrm{~S}, \mathrm{~B}=2 \mathrm{~T}, \mathrm{C}=2 \mathrm{U}+1$. Then $\mathrm{A}=\mathrm{B}+\mathrm{C}$ becomes:

$$
2(\mathrm{~S}+\mathrm{T}-\mathrm{U})=1
$$

Since the left-hand side of the equation is even, the right side can't equal 1 , which is odd. So it is impossible for two terms to be even and one odd.

## APPENDIX A: TWO UNIQUE PRIMITIVE PYTHAGOREAN TRIPLES SOLUTIONS

Since A, B, and C are relatively prime, and any even number squared is even, it follows that $\mathrm{A}, \mathrm{B}$ and C cannot all be even. Since any odd number squared, is odd, from Lemma 1, it follows that of the three terms, A, B and C, two are odd and one is even.

Furthermore, C cannot be even (see Appendix B). Therefore, if a Pythagorean triple is primitive, then C must be odd, and of the terms A and B , one is odd and one is even. Without loss of generality, let A be odd, and let B be even, B $=2 \mathrm{~N}$. In Appendix C we prove that N must be even, so let $\mathrm{N}=2 \mathrm{~L}$ and, therefore, $\mathrm{B}=4 \mathrm{~L}$.
Since $\mathrm{C}>\mathrm{A}$, and both A and C are odd, we define $\mathrm{C}=\mathrm{A}+2 \mathrm{G}$, and the Pythagorean triple becomes Equation 1:

$$
4 \mathrm{~L}^{2} / \mathrm{G}=\mathrm{A}+\mathrm{G}
$$

Since $A$ and $G$ are integers, $4 L^{2} / G$ must be an integer. There are only 4 possible ways
$4 L^{2} / G$ can be an integer ${ }^{\mathrm{e}}$.
Case 1: $\mathrm{G}=1$.
Case 2: $\mathrm{G}=4$.
Case 3: $\mathrm{G}=2$.
Case 4: $G$ and $L$ have a common factor.
For Case 1, Equation1 becomes $A=4 \mathbf{L}^{\mathbf{2}} \mathbf{- 1}$. Since $C=A+2 G$, we get that $C=\mathbf{4} L^{\mathbf{2}}+\mathbf{1}$.
Since $L$ is any integer, we substitute $I$ for $L$.

For Case 2, Equation1 becomes $L^{2}=A+4$. By construction Ais odd, thus $L^{2}$ must be odd (Lemma 1) so define $L=2 P+1$. We then get $A=(\mathbf{2 P}+\mathbf{1})^{\mathbf{2}}-\mathbf{4}$. Since $\mathrm{C}=\mathrm{A}+2 \mathrm{G}$, we get that $\mathbf{C}=(\mathbf{2 P + 1})^{\mathbf{2}}+\mathbf{4}$. Since, $B=4 L$, we get $B=\mathbf{4}(\mathbf{2 P + 1})$. Since $P$ is any integer, we substitute I for $P$.

## APPENDIX B: C CANNOT BE EVEN

If C is even, define $\mathrm{C}=2 \mathrm{Y}$. Since both A and B are odd, define $\mathrm{A}=\mathrm{B}+2 \mathrm{X}$, where $\mathrm{X} \geq 0$.
The Pythagorean triple then becomes

$$
\mathrm{B}^{2} / 2+\mathrm{BX}+\mathrm{X}^{2}=\mathrm{Y}^{2}
$$

Since all the terms besides $\mathrm{B}^{2} / 2$ are integers, $\mathrm{B}^{2} / 2$ must be in integer. $\mathrm{So}, \mathrm{B}$ must be even.
But this contradicts our assumption that B is odd. So, it is impossible for C to be even.

## APPENDIX C: PROOF THAT WHEN B $=\mathbf{2 N}$, N MUST BE EVEN

Assume N is odd, so $\mathrm{N}=2 \mathrm{G}+1$. Since $\mathrm{C}>\mathrm{A}$, let $\mathrm{C}=\mathrm{A}+\mathrm{X}$. The Pythagorean triple then becomes

$$
2(2 \mathrm{G}+1)^{2}=\mathrm{AX}+\mathrm{X}^{2} / 2
$$

Since all the terms other than $\mathrm{X}^{2} / 2$ are integers, $\mathrm{X}^{2} / 2$ must be in integer. Therefore, X must be even. Define $X=2 P$.

Substituting 2P for X and simplifying yields

$$
(2 \mathrm{G}+1)^{2}=\mathrm{AP}+\mathrm{P}^{2}
$$

Since $(2 \mathrm{G}+1)^{2}$ is odd, From Lemma 1 of the two terms AP or $\mathrm{P}^{2}$, one must be odd and one must be even.
If P is even, then both AP and $\mathrm{P}^{2}$ are even. So, P cannot be even. If P is odd, $\mathrm{P}^{2}$ is odd and since by construction A is odd, AP is also odd, so P cannot be odd. Since it is impossible for P to not be even and not bze odd, it follows that N cannot be odd.

[^1]
[^0]:    *Professor, Stan Ross Department of Accountancy, Zicklin School of Business, Bernard Baruch, City University of New York, USA

[^1]:    ${ }^{\text {a }}$ In other words, there is no integer $\mathrm{Z}, \mathrm{Z}>1$, for which $\mathrm{A} / \mathrm{Z}, \mathrm{B} / \mathrm{Z}$ and $\mathrm{C} / \mathrm{Z}$ are all integers. Alternatively, this can be formulated as $\mathrm{GCD}(\mathrm{A}, \mathrm{B}, \mathrm{C})=1$ (where GCD is the greatest common denominator). This will only be true only if $\operatorname{GCD}(A, B)=1, \operatorname{GCD}(A, C)=1$ and $G C D(B, C)=1$. Since if any two of the terms have a common factor, $Z>1$, for instance, $A=Z D$ and $B=Z E$. Then we getD ${ }^{2}+E^{2}=(C / Z)^{2}$. Since $D$ and $E$ are both integers, $\mathrm{C} / \mathrm{Z}$ must be an integer, so Z is also a factor of C .
    ${ }^{\mathrm{b}}$ For an alternative formulation, see Douglas W. Mitchell. "85.27 An Alternative Characterisation of All Primitive Pythagorean Triples." The Mathematical Gazette, vol. 85, no. 503, 2001, pp. 273-275. JSTOR, JSTOR, www.jstor.org/stable/3622017.
    ${ }^{c}$ For solution 1: $N=1$ and $M=2$ I. For solution $2: N=2$ and $M=2 I+1$.
    ${ }^{\text {d }}$ All the triples in Solution 2 are different than the triples in Solution 1, since in Solution 1, C $=A+2$, while in Solution $2, \mathrm{C}=\mathrm{A}+8$.
    ${ }^{e}$ Case 3 is an impossible solution, since for $G=2$, Equation 1 becomes $2 L^{2}=A+2$. Since $2 L^{2}$ and 2 are both even, A must be even (Lemma 1). But by construction, $A$ is odd. So, Case 2 is impossible. We do not analyze Case 4.
