| :--- | :--- |
|  | In a graph theory we have use basis of the group like abelian group <br> and subgroup for intersection. An intersection containing a non- unit <br> element . We characterize certain classes of subgroup intersection <br> graphs corresponding to finite abelian groups. We check all its <br> solvable groups whose intersection graphs are triangle-free. <br> Surrounded the other results, we analysis all abelian groups whose <br> intersection graphs are complete. Finally, we study the intersection <br> graphs of cyclic groups. |

## CHAPTER 1

## DEFINITION 1.1.

Let $G$ be a group. The intersection graph $G(G)$ of $G$ is the undirected graph (without loops and multiple edges) whose vertices are in a one-to-one correspondence with all proper non-trivial subgroups of $G$ and two vertices are joined by an edge, if and only if the
corresponding subgroups of $G$ have a non- trivial intersection(ie, an intersection containing
a non- unit element).
We know that, for every finite cyclic group $n$, for each divisor $d$ of $n$ there exists a unique Sub group of order d.

## Example.1.2.

Consider the cyclic group of order 12(i.e, $\mathrm{Z}_{12}$ )

## Soln.

$\mathrm{Z}_{12}$ has 4 proper subgroups as follows:

## Example 1.3.

Consider the cyclic group of order 36 (i.e, $\mathrm{Z}_{36}$ )

## Soln.

$Z_{36}$ has proper subgroups as follows:

$$
\begin{aligned}
& \mathrm{H}_{1}=\{0,2,4 \ldots . .34\}, \\
& \mathrm{H}_{2}=\{0,3,6 \ldots . .33\}, \\
& \mathrm{H}_{3}=\{0,4,8 \ldots .32\},
\end{aligned}
$$

$$
\begin{aligned}
\mathrm{H}_{4} & =\{0,6,12, \ldots .30\}, \\
\mathrm{H}_{5} & =\{0,9,18,27\}, \\
\mathrm{H}_{6} & =\{0,12,24\}, \\
\mathrm{H}_{7} & =\{0,18\} .
\end{aligned}
$$

$\mathrm{H}_{1}$

## Example 1.4.

Consider cyclic group of order 30 (ie, $\mathrm{Z}_{30}$ ).

## Soln.

$Z_{30}$ has 6 proper subgroups as follows:

$$
\begin{aligned}
& \mathrm{H}_{1}=\{0,2,4 \ldots \ldots 28, \\
& \mathrm{H}_{2}=\{0,3,6 \ldots .27\}, \\
& \mathrm{H}_{3}=\{0,5,10, \ldots 25\}, \\
& \mathrm{H}_{4}=\{0,6,1218,24\}, \\
& \mathrm{H}_{5}=\{0,10,20\}, \\
& \mathrm{H}_{6}=\{0,15\} .
\end{aligned}
$$

## Lemma 1.5.

Any finite non-trivial abelian group contains a cyclic subgroup whose order in a prime number.

## Proof.

Any finite abelian group can be expressed as a direct product of a primary cyclic groups.
ie, cyclic groups of the order equal to a power of a prime number.
If a is the generator and $\mathrm{p}^{\alpha}$ the order f any of these primary cyclic groups, then it is subgroup generated by $\mathrm{a}^{\mathrm{pa-1}}$ is cyclic and has the order p , which is a prime number.

Evidently, a primary cyclic group can contain only one such subgroup.

## Lemma 1.6.

The vertex independence number of the graph GG is equal to the maximal number of prime order subgroups of G.

## Proof.

Two distinct prime order subgroups of G have always a trivial intersection .
Because such groups contain only one proper subgroup, namely the trivial one.

Therefore any system of prime order subgroups of G corresponds to an independent set in G (G). Now, let us have a maximal independent set in $G$ (G). Any vertex of this set corresponds to a subgroup G: this subgroup has a prime order subgroup lemma, As any two subgroups of G corresponding to vertices of this independent set have trivial intersection, the prime order subgroups in subgroups of G corresponding to distinct vertices of this set must be distinct.

This implies that an independent set in $G(G)$ corresponds to a subgroup of $G$ containing more than one prime order subgroup, the cardinality of this independent set is less than the independence number of the graph $G(G)$.

## Corollary 1.7.

A vertex of $G(G)$ corresponds to a primary cyclic subgroup of $G$. If and only if it belongs to some independent set of $G(G)$ of maximal cardinality.

## Lemma 1.8.

Let $G$ be a finite abelian group which is not a direct of a product of two prime order groups Let $\mathrm{u}, \mathrm{v}$ be two vertices of $\mathrm{G}(\mathrm{G})$ not joined by an edge and corresponding to primary cyclic subgroups $U$, $B$ of $G(G)$. Then the orders of $U$ and $B$ are powers of different prime numbers, if and only if there exists a vertex w in $G(G)$ joined with both $u$ and $v$ and with no vertex which is not joined with $u$ and $v$.

## Proof.

Let the orders of U and B be powers of different prime numbers.
Let $W$ be the subgroup of $G$ generated by the prime order subgroups of $U$ and $B$.
The subgroup W is a proper subgroup of, because G is not a direct product of two prime order groups.

The vertex w of GG corresponding to $(\mathrm{W})$ is evidently joined with both u and v .
Now let some vertex $x$ of $G(G)$ be joined with w .

This means that x correspondence to a subgroup X of G such that $\mathrm{X} \cap \mathrm{W} \neq\{e\}$.
Let $\mathrm{e} \neq \mathrm{a} \epsilon \mathrm{X} \cap \mathrm{W}$; then $\mathrm{a}=\mathrm{b}^{\mathrm{m}} \mathrm{c}^{\mathrm{n}}$, where $\mathrm{b}, \mathrm{c}$ are generators of U and B respectively.
If $\mathrm{p}, \mathrm{q}$ are orders of $\mathrm{b}, \mathrm{c}$ respectively, take $\mathrm{a}^{\mathrm{p}}=\mathrm{b}^{\mathrm{mp}} \mathrm{c}^{\mathrm{np}}$.
This is equal to $\mathrm{c}^{\mathrm{np}}$, because $\mathrm{b}^{\mathrm{mp}}=\mathrm{c}$.
According to the assumption , $\mathrm{p}, \mathrm{q}$ are relatively prime.
Therefore $\mathrm{c}^{\mathrm{np}}=\mathrm{e}$ implies $\mathrm{np} \equiv 0(\bmod (\mathrm{q}))$ and $\mathrm{n} \equiv 0(\bmod (\mathrm{q}))$ which means $\mathrm{c}^{\mathrm{n}}=\mathrm{e}$ and $a=b^{m}$.

We have either $a=b^{m}$, or $^{p}=c^{n p} \neq e$.
As both a and $\mathrm{a}^{\mathrm{p}}$ are in $(\mathrm{X})$,this means either $\mathrm{X} \cap \mathrm{U} \neq\{e\}$, or $\mathrm{X} \cap \mathrm{B} \neq\{e\}$ and x is joined either with $u$ or with $v$.

Now, let the orders of $U$ and B be powers of the same prime number $p$ : Let the order of $U$ be $\mathrm{p}^{\alpha}$, the order of B be $\mathrm{p}^{3}$.

Without loss of generality, $\alpha \leq \beta$.
Let b,c be the generators of $U$ and $B$ respectively.
Then $\mathrm{c}^{\mathrm{p} \mathrm{\beta-} \mathrm{\alpha}}$ has the same order $\mathrm{p}^{\alpha}$ as b and the product of $\mathrm{bc}^{\mathrm{p} \mathrm{\beta}-\alpha}$ has also this order.
The primary cyclic subgroup generator by $\mathrm{bc}^{\mathrm{p} \beta-\alpha}$ will be denoted by W : evidently, it has trivial intersection with U and B.

Let S be a subgroup of G which has non- trivial intersection with both U and B ;
Thus $X \cap U \ni b^{r}, X \cap B \ni \mathrm{c}^{8}$, where $\mathrm{r}, \mathrm{s}$ are positive integers, $\mathrm{r} \equiv 0\left(\operatorname{modp}^{\alpha}\right)$,
$\mathrm{s} \equiv 0\left(\operatorname{modp}^{\beta}\right)$. Then X contains also the product $\left(\mathrm{bc}^{\mathrm{p} \beta-\alpha}\right)$, where t is the least common multiple of $r$ and of the greatest common divisor of $\mathrm{p}^{\beta-\alpha}$ and s .

This element evidently different from e and belongs to W .
Therefore $\mathrm{X} \cap \mathrm{W} \neq\{\mathrm{e}\}$ and x is joined also with w .
As X was chosen arbitrarily, the assertion is proved.
Hence the proof.

## Lemma 1.9.

Let $G$ be a direct product of two prime order groups. If these groups have different orders, the graph $G(G)$ consists of two isolated vertices. If these groups have equal order, the graph $G(G)$ contains more than two vertices.

## Lemma 1.10.

Let G be a finite Abelian group whose order is a power of a prime number p . Then the vertex independence number of $\mathrm{G}(\mathrm{G})$ is equal to $\sum_{i=0}^{n-1} p^{\mathrm{i}}$, where n is the number of direct factors in the expression of G as a direct product of primary cyclic groups.

## Proof.

Let $\mathrm{G}_{1} \ldots . . \mathrm{G}_{\mathrm{n}}$ be the factors in the mentioned direct product.
Evidently G contains exactly one prime order subgroup S for $\mathrm{i}=1, \ldots \mathrm{n}$;
Therefore it contains $\mathrm{p}-1$ elements of prime order .
All elements of the order $p$ are products of these elements; thus their number is $p^{n}-1$.
As any prime order subgroup $G$ has the order $p$ and thus $p-1$ non - unit elements which are all of the order p and as any two of such subgroup have trivial intersection, there are $\left(\mathrm{p}^{\mathrm{n}}-1\right) /\left(\mathrm{p}^{\mathrm{n}}-1\right)=\sum_{i=0}^{n-1} p^{\mathrm{i}}$ prime order subgroups of G.

According to lemma, this is also the vertex independence number of the graph $G(G)$,
We can find $\sum_{i=0}^{n-1} p^{i}$ for any of these Sylow subgroups.

## Theorem 1.11.

Let G be a finite Abelian group. Let $\mathrm{G}(\mathrm{G})$ be its intersection graph.
Knowing the graph $G(G)$, we can determine the number of factors in the expression of G as a direct product of Sylow groups and the intersection graph for any of these sylow groups.

Moreover, for any of these sylow subgroups of G, we can determine the number $\sum_{i=0}^{n-1} p^{\mathrm{i}}$,
where p is the prime number whose power is the order of this group and n the number of factors in its expression as a direct product of primary cyclic groups.

## Proof .

Let $G(G)$ be given . We find an independent set A of vertices in $G(G)$ maximal cardinality: it corresponds to a system of primary cyclic subgroups of $G$ with pairwise trivial intersection (Lemma and its corollary).

According to Lemma, we shall decide for an pair of vertices of A whether the orders of the subgroup of G corresponding to these vertices are powers of the same prime number or not

Now, let B be a subset of A such that all vertices of B correspond to the subgroups ofG whose orders are powers of the same prime number $p$ and any vertex of $A-B$ corresponds to a subgroup whose order is a power of another prime number.

The subgraphs of G corresponding to vertices of $\mathrm{A}-\mathrm{B}$ belong to other sylow subgroup.
The mentioned sylow subgroup contains as its non-trivial subgroups exactly all subgroups of $G$ which have a non-trivial intersection with atleast one subgroup corresponding to a vertex of S and have trivial intersections with all subgroups corresponding to vertices A B .

This can be proved simply .
The subgroups corresponding to vertices of B contain as their subgroups all subgroups of G of the order p (any of them contains exactly one such subgroup);

Therefore any subgroup of $G$ of the order equal to a power of $p$ must have a non-trivial intersection with some of them.

Now, if a subgroup of $G$ has a non-trivial intersection with a subgroup corresponding to a vertex of $\mathrm{A}-\mathrm{B}$, this intersection contains an element whose order is equal to a power of a
prime number different from p and thus this subgroup is not a subgroup of the mentioned sylow subgroup.

The intersection graph of this sylow subgroup is therefore the subgraph of $S(G)$ induced by the
vertex set consisting of $B$ and all vertices set of $G(G)$ which are joined with atleast one vertices
of $B$ with no vertex of $A-B$.
In this way we can construct intersection graphs of all sylow subgroups of $G$ and thus also recognize the number of these subgroups .

According to Lemma,
Hence the proof

## CHAPTER 2

## INTERSECTION GRAPH OF SUBGROUPS

## OF FINITE GROUPS

## Definition 2. 1.

If there exist non trivial subgroups $L_{1} \ldots L_{n}$ of $G$ such that
$\mathrm{H} \sim \mathrm{L}_{1}, \mathrm{~L}_{1} \sim \mathrm{~L}_{2} \ldots \mathrm{~L}_{\mathrm{n}-1} \sim \mathrm{~L}_{\mathrm{n}}, \mathrm{L}_{\mathrm{n}} \sim \mathrm{K}$,then we say that H and K are connected by the chain $\mathrm{H} \sim \mathrm{L}_{1} \sim \mathrm{~L}_{2} \sim \ldots \sim \mathrm{~L}_{\mathrm{n}} \sim \mathrm{K}$. Clearly, in this case $\rho(\mathrm{H}, \mathrm{K}) \leq \mathrm{n}+1$.

The Dihedral group of order 2 n .
$\mathrm{D}_{2 \mathrm{n}}=<\mathrm{r}, \mathrm{s}>\left\{1, \mathrm{r}, \mathrm{r}^{2}, \mathrm{r}^{3}, \ldots, \mathrm{r}^{\mathrm{n}-1}, \mathrm{~s}, \mathrm{sr}, \mathrm{sr}^{2}, \mathrm{sr}^{3}, \ldots, \mathrm{sr}^{\mathrm{n}-1}\right\}$,
where $\mathrm{r}^{\mathrm{n}}=1, \mathrm{~s}^{2}=1$ and $\mathrm{r}^{\mathrm{i}} \mathrm{s}=\mathrm{sr}^{\mathrm{n}-\mathrm{i}}$.

## Note 2.2.

For each positive integer $n$, let $d(n)$ denote the number of positive divisors of $n$.
And let $\sigma$ denote the sum of the positive divisors of $n$. The number of subgroups of dihedral
group $\mathrm{D}_{2 \mathrm{n}}(\mathrm{n} \geq 3)$ is $\mathrm{d}(\mathrm{n})+\sigma(\mathrm{n})$.

## Example 2.3.

Consider the dihedral group order 8 .
$D_{8}=\langle r, s\rangle=\left\{1, r, r^{2}, r^{3}, r^{4}, s, s r, s r^{2}, \mathrm{sr}^{3}, \mathrm{sr}^{4}\right\}$, where $\mathrm{r}^{4}=1, \mathrm{~s}^{2}=1$
The proper sub group of $\mathrm{D}_{8}$ are

$$
\begin{aligned}
& \mathrm{H}_{1}=\left\{1, \mathrm{r}^{2}\right\}, \\
& \mathrm{H}_{2}=\left\{1, \mathrm{r}^{2}, \mathrm{~s}, \mathrm{sr}^{2}\right\}, \\
& \mathrm{H}_{3}=\left\{1, \mathrm{r}^{2}, \mathrm{sr}, \mathrm{sr}^{3}\right\}, \\
& \mathrm{H}_{4}=\left\{1, \mathrm{r}, \mathrm{r}^{2}, \mathrm{r}^{3}\right\}, \\
& \mathrm{H}_{5}=\{1, \mathrm{~s}\}, \\
& \mathrm{H}_{6}=\{1, \mathrm{sr}\}, \\
& \mathrm{H}_{7}=\left\{1, \mathrm{sr}^{2}\right\}, \\
& \mathrm{H}_{8}=\left\{1, \mathrm{sr}^{3}\right\},
\end{aligned}
$$

## Example 2.4.

The quarternion group of order 8 .

## Soln.

$$
\mathrm{Q}_{8}=\{ \pm 1, \pm \mathrm{i}, \pm \mathrm{j}, \pm \mathrm{k}\} \text {, where } \mathrm{ij}=\mathrm{k}, \mathrm{ji}=-\mathrm{k}, \mathrm{ik}=\mathrm{j}, \mathrm{ki}=-\mathrm{j}, \mathrm{jk}=\mathrm{i}, \mathrm{kj}=-\mathrm{i}
$$

and $o(i)=o(j)=o(k)=4$.

$$
\begin{aligned}
& \mathrm{H}_{1}=\{ \pm 1\} \\
& \mathrm{H}_{2}=\{ \pm 1, \pm \mathrm{i}\} \\
& \mathrm{H}_{3}=\{ \pm 1, \pm \mathrm{j}\} \\
& \mathrm{H}_{4}=\{ \pm 1, \pm \mathrm{k}\} .
\end{aligned}
$$

Q8

## Example 2.5.

Consider the dihedral group order 12.

## Soln.

$$
\begin{aligned}
\mathrm{D}_{12}=\langle r, s\rangle & =\left\{1, \mathrm{r}, \mathrm{r}^{2}, \mathrm{r}^{3}, \mathrm{r}^{4}, \mathrm{r}^{5}, \mathrm{r}^{6}, \mathrm{~s}, \mathrm{sr}, \mathrm{sr}^{2}, \mathrm{sr}^{3}, \mathrm{sr}^{4}, \mathrm{sr}^{5}, \mathrm{sr}^{6}\right\}, \text { where } \mathrm{r}^{3}=1, \mathrm{~s}^{2}=1 . \\
\mathrm{H}_{1} & =\left\{1, \mathrm{r}^{3}\right\}, \\
\mathrm{H}_{2} & =\left\{1, \mathrm{r}^{3}, \mathrm{~s}, \mathrm{sr}^{3}\right\} \\
\mathrm{H}_{3} & =\left\{1, \mathrm{r}^{2}, \mathrm{r}^{4}\right\}, \\
\mathrm{H}_{4} & =\{1, \mathrm{~s}\},
\end{aligned}
$$

$$
\begin{aligned}
& \mathrm{H}_{5}=\{1, \mathrm{sr}\}, \\
& \mathrm{H}_{6}=\left\{1, \mathrm{sr}^{2}\right\}, \\
& \mathrm{H}_{7}=\left\{1, \mathrm{sr}^{3}\right\}, \\
& \mathrm{H}_{8}=\left\{1, \mathrm{sr}^{4}\right\}, \\
& \mathrm{H}_{9}=\left\{1, \mathrm{sr}^{5}\right\}, \\
& \mathrm{H}_{10}=\left\{1, \mathrm{r}_{2}^{2}, \mathrm{r}^{3}, \mathrm{r}^{4}, \mathrm{r}^{5}\right\}, \\
& \mathrm{H}_{11}=\left\{1, \mathrm{r}^{2}, \mathrm{r}^{4}, \mathrm{~s}, \mathrm{sr}^{2}, \mathrm{sr}^{4}\right\}, \\
& \mathrm{H}_{12}=\left\{1, \mathrm{sr}^{2}, \mathrm{sr}^{3}, \mathrm{sr}^{4}\right\}, \\
& \mathrm{H}_{13}=\left\{1, \mathrm{r}^{3}, \mathrm{sr}^{2}, \mathrm{sr}^{5}\right\}, \\
& \mathrm{H}_{14}=\left\{1, \mathrm{r}^{2}, \mathrm{r}^{4}, \mathrm{sr}, \mathrm{sr}^{3}, \mathrm{sr}^{5}\right\},
\end{aligned}
$$

## Lemma 2.6.

If G is connected, then the diameter $\delta(\mathrm{G})$ is equal to $\max \{\rho(\mathrm{P}, \mathrm{Q})$ : both $\mathrm{P}, \mathrm{Q}$ are subgroups of prime order of G\}.

## Lemma 2.7.

Let $B$ be a block of $G$ and $M$ be a proper subgroup of the group $G$.
If $B \cap M \neq 1$, then $M \subseteq B$.

## Lemma 2.8.

Let B be a block of G .Then B is a subgroup of G or a normal subset of G.

## Lemma 2.9.

Let $G$ be disconnected and $B=\left\{B_{1}, B_{2}, \ldots . . B_{1}\right\}$ be the set of all the subgroup blocks of G . Then any conjugate of B , is connected in B for $\mathrm{i}=1 \ldots .1$.

## Lemma 2.10.

If G is not a simple group, then one of the following cases occurs:
(1) The diameter $\delta(\mathrm{G}) \leq 4$.
(2) G is $\mathrm{Z}_{\mathrm{p}} \times \mathrm{Z}_{\mathrm{q}}$, where $\mathrm{p}, \mathrm{q}$ are primes.
(3) G is a Frobenius group whose complement is a group of prime order and the kernel is a minimal normal subgroup.

## Proof.

Suppose that N is a non-trivial proper normal subgroup of G .
By Lemma, the required result $\delta(\mathrm{G}) \leq 4$ is equivalent to $(\mathrm{P}, \mathrm{Q}) \leq 4$ for any prime order subgroups $\mathrm{P}, \mathrm{Q}$ with $\mathrm{P} \neq \mathrm{Q}$.

Let $|P|=|\langle a\rangle|=\mathrm{p}$ and $|Q|=|\langle b\rangle|=\mathrm{q}$.

## Case 1:

$$
\mathrm{PN}=\mathrm{G} .
$$

(a) If $\mathrm{Q} \cap \mathrm{N}=\langle b\rangle \cap \mathrm{N}=1$, then $\mathrm{b} \in \mathrm{G} / \mathrm{N} \cong \mathrm{P}$, the order of every element of $\mathrm{G} \backslash \mathrm{N}$ is a multiple of $p$.

So the order of b is p ,that is $\mathrm{o}(\mathrm{b})=\mathrm{p}=\mathrm{q}$.
If $\mathrm{C}_{\mathrm{G}}(\mathrm{a})=\mathrm{G}$, then $\mathrm{G}=\mathrm{P} \times \mathrm{N}$, Since $\mathrm{o}(\mathrm{a})=\mathrm{o}(\mathrm{b})=\mathrm{p}$, we can assume that $\mathrm{Q}=\langle(a, x)\rangle$, where $\mathrm{x} \in \mathrm{N}$ and $\mathrm{o}(\mathrm{x})=\mathrm{p}$.

Now, we set $\mathrm{H}=\{(\mathrm{y}, \mathrm{z}): \mathrm{y} \in\langle a\rangle, \mathrm{z} \in\langle x\rangle\}$.
If $|N| \neq \mathrm{p}$, then H is a proper subgroup of G .

So that we have a chain $\mathrm{P} \sim \mathrm{H} \sim \mathrm{Q}$.
Thus $\rho(\mathrm{P}, \mathrm{Q}) \leq 2$.
Certainly, when G is $\mathrm{Z}_{\mathrm{P}} \times \mathrm{Z}_{\mathrm{P}}$, there are $\mathrm{p}+1$ nontrivial.
(i.e., the intersection graph $\Gamma(\mathrm{G})$ is the $\mathrm{p}+1$ isolated vertices graph .

If $\mathrm{C}_{\mathrm{G}}(\mathrm{b})=\mathrm{G}$, then $\langle b\rangle \triangleleft \mathrm{G}$.
Since $\mathrm{b} \neq \mathrm{N}$, we have $\mathrm{G}=\langle b\rangle \times \mathrm{N}$ by virtue of $|G|=\mathrm{p}|N|$.
So we can assume that $\langle a\rangle=\langle b, x\rangle$, where $\mathrm{x} \in \mathrm{N}$ and $\mathrm{o}(\mathrm{x})=\mathrm{p}$.
Similarly we choose a group $\mathrm{H}=\{(\mathrm{y}, \mathrm{z}): \mathrm{y} \in\langle b\rangle, \mathrm{z} \in\langle x\rangle\}$.
When $|N| \neq \mathrm{p}$, then H is a proper subgroup of G .
So, P and Q are connected by a chain $\mathrm{P}-\mathrm{H}-\mathrm{Q}$.
Thus we have also $\rho(\mathrm{P}, \mathrm{Q}) \leq 2$.
Now we suppose that $\mathrm{C}_{\mathrm{G}}(\mathrm{a}) \neq \mathrm{G}$ and $\mathrm{C}_{\mathrm{G}}(\mathrm{b}) \neq \mathrm{G}$.
If $\mathrm{C}_{\mathrm{G}}(\mathrm{a}) \cap \mathrm{N} \neq 1$ and $\mathrm{C}_{\mathrm{G}}(\mathrm{b}) \cap \mathrm{N} \neq 1$, then $\langle a\rangle \sim \mathrm{C}_{\mathrm{G}}(\mathrm{a}) \sim \mathrm{N}$ and $\langle b\rangle \mathrm{C}_{\mathrm{G}}(\mathrm{b}) \sim \mathrm{N}$,
So $\langle a\rangle \sim \mathrm{C}_{\mathrm{G}}(\mathrm{a}) \sim \mathrm{N} \sim \mathrm{C}_{\mathrm{G}}(\mathrm{b}) \sim\langle b\rangle$.
Then we have $(\mathrm{P}, \mathrm{Q}) \leq 4$.
If $\mathrm{C}_{\mathrm{G}}(\mathrm{a}) \cap \mathrm{N}=1$ or $\mathrm{C}_{\mathrm{G}}(\mathrm{b}) \cap \mathrm{N}=1$, we may assume without loss of generality,
That $\mathrm{C}_{\mathrm{G}}(\mathrm{a}) \cap \mathrm{N}=1$, then $\langle a\rangle$ acts non-fixed point on the subgroup N .
Thus $\mathrm{G}=\mathrm{N}:\langle a\rangle$ is a Frobenius group.
Clearly, if N is not a minimal normal subgroup of G , then we can choose a non-trivial normal subgroup $\mathrm{N}_{1}$ of N such that $\mathrm{N}_{1} \sim \mathrm{G}$.

So we get a chain $\langle a\rangle \sim \mathrm{N}_{1}(\mathrm{a}) \sim \mathrm{N}_{1}(\mathrm{~b}) \sim\langle b\rangle$, hence we have $\rho(\mathrm{P}, \mathrm{Q}) \leq 3$.
Certainly, if N is minimal normal subgroup of G , then G satisfies the requirement (3).
(b) Case $\mathrm{Q} \leq N$

If $\mathrm{C}_{\mathrm{G}}(\mathrm{a})=\mathrm{G}\left(\right.$ or $\left.\mathrm{C}_{\mathrm{G}}(\mathrm{b})=\mathrm{G}\right)$, then $\mathrm{p} \triangleright \mathrm{G}($ or $\mathrm{Q} \triangleright \mathrm{G})$.
Hence, when $\mathrm{PQ} \neq \mathrm{G}$, we have a chai $\mathrm{n} \mathrm{P} \sim \mathrm{PQ} \sim \mathrm{Q}$ and then $\rho(\mathrm{P}, \mathrm{Q}) \leq 2$.

Certainly, if $\mathrm{PQ}=\mathrm{G}$, then $\mathrm{G}=\mathrm{P} \times \mathrm{Q}$ or $\mathrm{G}=\mathrm{Q}: \mathrm{P}$ is Frobenius group and
Hence the intersection graph of $G$ is the empty graph on two or $q+1$ vertices.
Next, we consider the case of $\mathrm{C}_{\mathrm{G}}(\mathrm{a}) \neq \mathrm{G}$ and $\mathrm{C}_{\mathrm{G}}(\mathrm{b}) \neq \mathrm{G}$.
If $\mathrm{C}_{\mathrm{G}}(\mathrm{a}) \cap \mathrm{N} \neq\{1\}$, then $\mathrm{P} \sim \mathrm{C}_{\mathrm{G}}(\mathrm{a}) \sim \mathrm{N} \sim \mathrm{Q}$.
Hence, we have $\rho(\mathrm{P}, \mathrm{Q}) \leq 3$.
If $\mathrm{C}_{\mathrm{G}}($ a $) \cap \mathrm{N}=\{1\}$, then P acts as a group N of fixed point free automorphism.
Thus $\mathrm{G}=\mathrm{N}:\langle\mathrm{a}>$ is a Frobenius group.
Similarity to the case (a), we have that N is a minimal normal subgroup of G .
Hence G satisfies the requirement (3).
Similarity, if QN = G, then we have the same results.
Case 2 :

$$
\mathrm{PN} \neq \mathrm{G} \text { and } \mathrm{QN} \neq \mathrm{G} .
$$

P and Q can be joined by the same $\mathrm{P} \sim \mathrm{PN} \sim \mathrm{QN} \sim \mathrm{Q}$.
Thus $\rho(\mathrm{P}, \mathrm{Q}) \leq 3$.

## Assertion I.

If $\mathrm{n}>4$, then the alternating group $\mathrm{A}_{\mathrm{n}}$ is connected and $\delta\left(\mathrm{A}_{\mathrm{n}}\right) \leq 4$.

## Proof.

By lemma, it suffices to prove that $\rho(\mathrm{P}, \mathrm{Q}) \leq 4$ for any subgroups P and Q of prime order.

Now, we can assume that P and Q are contained in maximal subgroups $\mathrm{M}_{1}$ and $\mathrm{M}_{2}$ respectively.

If $\mathrm{M}_{1} \cap \mathrm{M}_{2} \neq 1$, then $\mathrm{P} \sim \mathrm{M}_{1} \sim \mathrm{M}_{2} \sim \mathrm{Q}$, so that $\rho(\mathrm{P}, \mathrm{Q}) \leq 3$.
Next we will prove that the order of every maximal subgroup of $A_{n}$ with $n \geq 5$ is more than n .

For the cases of $\mathrm{n}=5$ and 6 , this is true by inspection

Now, suppose that $\mathrm{n} \geq 7$.
Consider $\mathrm{A}_{\mathrm{n}}$ in its natural degree n action.
If a maximal subgroup $M$ is intransitive, say has an orbit of length $k$, then
$|\mathrm{M}| \geq \mathrm{k}!(\mathrm{n}-\mathrm{k})!/ 2>\mathrm{n}$.
So M is transitive.
If $|\mathrm{M}|=\mathrm{n}$, then M is regular.
Each automorphism of $M$ is induced by conjugation with some element from $S_{n}$.
This if $M$ is maximal in $A_{n}$, then the automorphism group of $M$ has order atmost 2 .
Consider inner automorphisms, so the order of $\mathrm{M} / \mathrm{Z}(\mathrm{M})$ is less than or equal to 2 , hence M is abelian.

From $\mid$ Aut $(M) \mid \leq 2$, we get $\mathrm{M}=\mathrm{Z}_{\mathrm{n}}$ with $\mathrm{n}=2,3$ or 6 , which is impossible.
Now return to our question.
If $M_{1} \cap M_{2}=1$, we choose a largest maximal subgroup $M$ of $A_{n}$, then it follows that
$\mathrm{M} \cap \mathrm{M}_{1} \neq 1$ and $\mathrm{M} \cap \mathrm{M}_{2} \neq 1$.
Indeed, otherwise ,if $\mathrm{M} \cap \mathrm{M}_{1}=1$, then $\left|\mathrm{MM}_{1}\right|=|M|\left|\mathrm{M}_{1}\right| /\left|\mathrm{M}_{1} \mathrm{M}_{1}\right|=|M| \mathrm{M}_{1} \mid>\mathrm{n} \cdot \mathrm{A}_{\mathrm{n}-1}=$ $\left|A_{n}\right|$,
a contradiction.
Hence $\mathrm{P} \sim \mathrm{M}_{1} \sim \mathrm{M}_{2} \sim \mathrm{Q}$, and consequently $\rho(\mathrm{P}, \mathrm{Q}) \leq 4$.

## Assertion II.

If G is a simple group of lie type or a sporadic simple group, then its intersection graph is connected.

## Proof.

Suppose that G has a disconnected intersection graphs.

Let the order of G be $p_{1}{ }^{e 1} p_{2}{ }^{e 2} \ldots . . p_{n}{ }^{\text {en }}$ and let $B_{1}, B_{2} \ldots . . B_{k}$ be blocks of $G$.
Now we choose a series of numbers $b_{1}, b_{2} \ldots . . b_{k}$ such that $p_{1}{ }^{\text {el }} l l b_{i}$ if and only if there is an
element of order $p_{1}$ in $B$ for $1=1,2 \ldots . n$ and $i=1,2, \ldots k$.
By Lemma, if some $B_{i}$ is a subgroup, then $B_{i}$ is a maximal subgroup and $B_{i}{ }^{g}$ is also a block of

G for every $\mathrm{g} \in \mathrm{G}$.
On the other hand, $N_{G}\left(B_{i}\right)=B_{i}$ since $B_{i}$ is maximal and $B_{i}$ is not a maximal subgroup.
If follows that $N_{G}\left(B_{i}{ }^{g}\right)=N_{G}\left(B_{i}\right)^{g}=B_{i}{ }^{g}$, and hence $B_{i} \cap B_{i}{ }^{g}=1$ for all $g \in G \backslash B_{i}$.
Thus G has a non-trivial normal subgroup by the well known Frobenius theorem, which contradicts the fact that G is a simple group .

So every $B_{i}$ is a normal subset of $G$ be Lemma.
Next we will prove, $\left(\mathrm{b}_{\mathrm{i}}, \mathrm{b}_{\mathrm{j}}\right)=1$ for $\mathrm{i} \neq \mathrm{j}$.
If for some $1 \leq 1 \leq n$ and $1 \leq i, j \leq k$ there exists $p_{1}$ such that $\mathrm{p}_{1}$ divides $\left(\mathrm{b}_{\mathrm{i}}, \mathrm{b}_{\mathrm{j}}\right)=1$, then there are $a \in B_{i}, b \in B_{j}$ satisfying $o(a)=o(b)=p_{1}$.

Obviously, there exit sylow $p_{1}$ subgroups $\mathrm{P}_{1}, \mathrm{P}_{2}$ of G containing $a$ and $b$ respectively.
Since $P_{1}$ and $P_{2}$ are conjugate, we set $P_{1}{ }^{h}=P_{2}$, then $P_{2}$ is contained in $B_{i}$ by Lemma, and hence $\mathrm{B}_{\mathrm{i}}, \mathrm{B}_{\mathrm{j}}$ are connected, a contradiction.

Therefore, $|G|=b_{1}, b_{2} \ldots b_{k}$ and $a \in B_{i}$ if and only if $o(a)$ divides $b_{i}$ for any $a \in G$.
Choose $M_{i}$ to be a maximal subgroup of $G$ in the block $B_{i}$ for $i=1,2, \ldots k$.
By the above arguments we have $\left(\left|\mathrm{M}_{1}\right|,\left|\mathrm{M}_{2}\right|\right)=1$ for $\mathrm{i} \neq \mathrm{j}$.
Hence for every prime pairs $p_{i}, p_{j}$, where $p_{i}$ divides $b_{i}$ and $p_{j}$ divides $b_{j}$ for $i \neq j$, we have that $G$ has no element of order $p_{i}, p_{j}$.

Now we define another graph A (G) of G called the prime graph G, whose vertices set is $\pi(\mathrm{G})=\{\mathrm{p}: \mathrm{p}$ is a divisor of $|G|\}$, vertices p and q in $\pi(\mathrm{G})$ are joined by an edge if and only
if there exists an element of order pq.
The classification of disconnected prime graphs of non - abelian simple groups.

Now let $\pi\left(b_{i}\right)=\left\{p: p\right.$ is a prime divisor of $\left.b_{i}\right\}$, then $\pi\left(b_{i}\right)$ is a prime graph component of G for $\mathrm{i}=1,2, \ldots \mathrm{k}$.

Assume that 2 is contained in $\pi\left(b_{1}\right)$.
If $G$ is a simple group of Lie type except $A_{1}(q)$, then $M_{i}$ is a maximal torus of $G$ for $i \geq$
2.

And hence $N_{G}\left(M_{i}\right) \cap B_{1} \neq 1$, hence $M_{i}$ is connected to $M_{1}$, a contradiction.
If G is $\mathrm{A}_{1}(\mathrm{q})$ with q odd, set $\pi\left(\mathrm{b}_{2}\right)=\pi(\mathrm{q})=\mathrm{p}$,then $\mathrm{M}_{2}$ is a elementary abelian p-group
And $M_{2}$ is a sylow $p$ subgroup of $G$, and we have $N_{G}\left(M_{2}\right) \neq M_{2}$ by the well-known Burnside theorem which states that a finite group $G$ satisfying $N_{G}(P)=C_{G}(P)$ for some abelian sylow p group P is p-nilpotent.

Thus $\mathrm{M}_{2}$ is not a maximal subgroup of G , a contradiction.
For the remaining cases when $M_{i}$ of $A_{1}(q)$ for $i \geq 2$ is a maximal torus, we will get similar
results.
If $G$ is a sporadic simple group or $F_{4}(2)^{\prime}$, the prime graph components vertices $\pi\left(b_{i}\right)$ with
$i \geq 2$ form a single point set $\{p\}$ and $M_{i}$ is a cycle Sylow -p subgroup of $G$.
Clearly, $\mathrm{M}_{\mathrm{i}}$ is not a maximal subgroup by the well-known Thomson theorem which asserts
that a finite group having an odd order nilpotent maximal subgroup must be solvable.
